It shows a simple line plot

It shows a simple line plot

It shows a simple line plot

It shows a simple line plot

simple Line plot:

```
# import matplotlib
```

```
import matplotlib.pyplot as plt
```

```
# sample data
```

```
x = [1, 2, 3, 4, 5]
```

```
y = [10, 12, 5, 8, 9]
```

```
# create a line plot
```

```
plt.plot(x, y)  # Linestyle = ':'
```

```
# customize the plot  # color = 'blue',
```

```
plt.title('sample Line plot')
```

```
plt.xlabel('x-axis')
```

```
plt.ylabel('y-axis')
```

```
# show the plot
```

```
plt.show()
```

# Scatter plot

Scatter plot shows the relationship between two or more variables.

It represents data on a Cartesian plane.

It works based on two conditions.

⇒ x depends on y

⇒ Independent variable (x-axis)  
(Dependent variable) (y-axis)

It works with two types of data.

simple scatter plots:

```
import matplotlib.pyplot as plt
```

```
x = [1, 2, 3, 4, 5]
```

```
y = [10, 12, 5, 8, 9]
```

```
# create a scatter plot
```

```
plt.scatter(x, y, label = 'data points', colour = 'blue',  
            marker = 'o')
```

```
# customize the plot.
```

```
plt.title('simple scatter plot')
```

```
plt.xlabel('x-axis')
```

```
plt.ylabel('y-axis')
```

```
plt.legend()
```

```
plt.show()
```

simple scatter plot.

data access engine

Bar chart - the so to say different types

\* Bars can be categorized  
horizontally or vertically

\* It shows the data representation

'data' - symbol of data, 'data' - label, 'y' - axis, 'x' - axis, 'data' - label

('x' = horizontal)

the data is represented as

('x' data access engine) data - label

('data - x') label - label

('data - y') label - label

() label - label

() label - label

## simple Bar chart

```
import matplotlib.pyplot as plt
```

```
# sample data
```

```
paste = ['colgate', 'Pepsodent', 'Closeup', 'Dabur red']
```

```
Sales = [120, 80, 40, 180]
```

```
# create a column chart
```

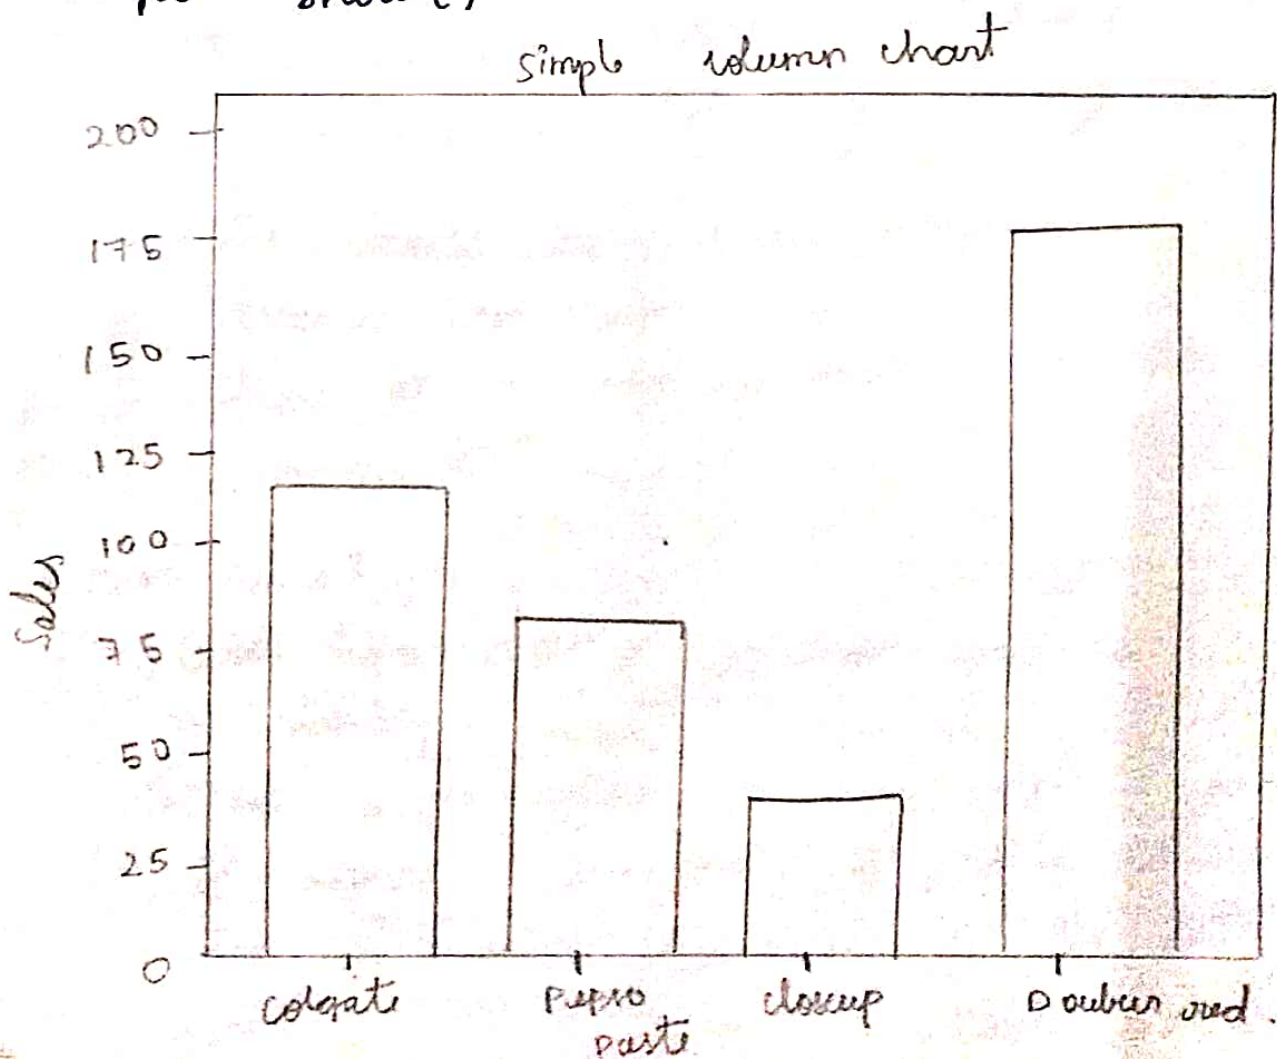

```
plt.bar(paste, Sales, color='green')
```

```
plt.title('simple column chart')
```

```
plt.xlabel('paste')
```

```
plt.ylabel('Sales')
```

```
plt.show()
```

trails not done

try to follow different trails

start again #

['best value', 'quality', 'energy', 'depth'] = start

[0.81, 0.4, 0.8, 0.51] = sub2

trails number a check #

('merge' = make, sub2, start) mod. try

('trails number depth') ; this, try

('start') sub/x = try

('sub2') sub/y = try

()-work . try

## Visualizing errors:

- > Visualizing errors in your data is essential for understanding the uncertainty or variability associated with your measurements.
- > Matplotlib provides various ways to visualize errors, and one common approach is to use error bars.
- > uncertainty (in the context of data and measurements) refers to the lack of exact knowledge about a quantity or value.
- > It represents the range of possible values that a measurement or data point might have due to factors such as measurement errors, variations, or limitations in data collection processes.
- > The choice of visualization method depends on your data, goals, and the type of uncertainty you want to communicate.

## Error Bars:

- > Error bars are a common way to visualize uncertainty.
- > They can be added to data points in plots to represent the range of possible values or the standard deviation of the data.  
(Line, bar, scatter plots)

sample code for Errorbar:

```
import matplotlib.pyplot as plt
import numpy as np

# Sample data
x = np.arange(1, 6)
y = np.array([10, 12, 5, 8, 9])
y_err = np.array([1, 2, 1, 2, 1]) # Eg error values.
```

# Create a simple line plot with error bars.

```
plt.errorbar(x, y, yerr = y_err, fmt = 'o',
             colour = 'b', capsize = 4)
```

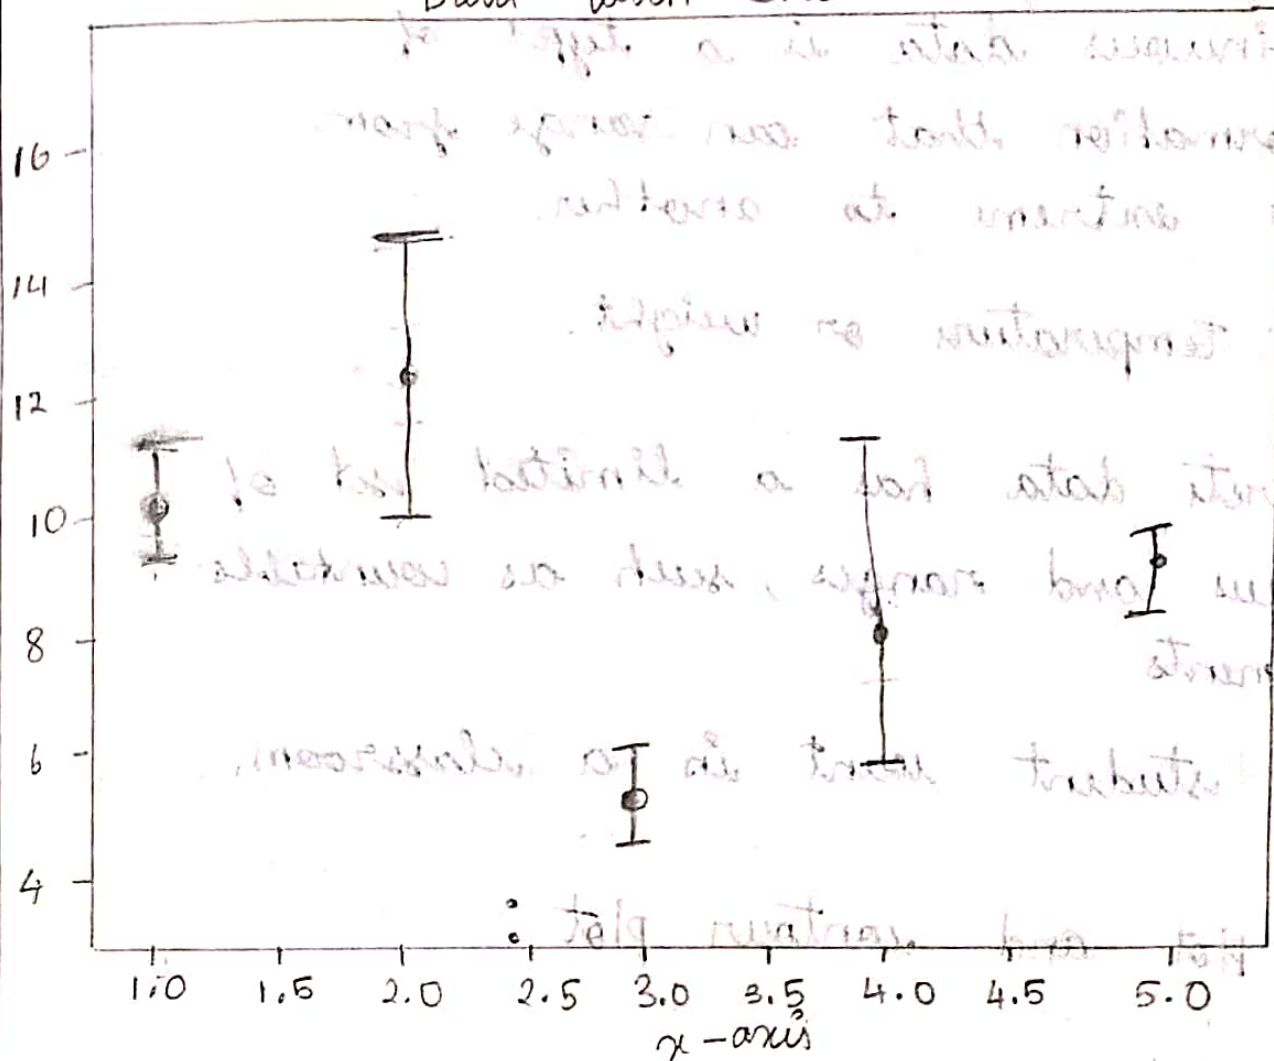

# Customize the plot.

```
plt.title('Data with Error Bars')
plt.xlabel('x-axis')
plt.ylabel('y-axis')
```

# show the plot

```
plt.show()
```

Data with Error Bars.

> This is usually used in scientific & Statistical Analysis to show the error (or) uncertainty for visualization.

### Distribution:

The distribution refers to how the data is clustered around certain values or ranges.

Use

gain insights into the characteristics and pattern of the data --> making informed decisions and predictions.

1. Continuous data is a type of information that can range from one extreme to another.

Eg: Temperature or weight.

2. Discrete data has a limited set of values and ranges, such as countable elements

Eg: student count in a classroom.

Density plot and contour plot:

Density plot:

two-dimensional colormap

A density plot is a graphical representation of data density to visualize the distribution of data points.

Eg: heat maps & 2D histograms.

contour plot:

A contour plot represents a three-dimensional surface by showing lines (contours) at constant values of the third dimension visualizing functions of two variables.

Eg: elevation maps, Temperature distributions.

To display three-dimensional data in two dimensions. using contours or color-coded regions. density and contour plots are commonly used in data visualization to represent the distribution of data points in 2-D space.

plt.contourf

plt.imshow

np.meshgrid function, which builds two-dimensional grids from one-dimensional array.

use:

- > Visualizing data density ✓
- > Identifying trends ✓
- > Spotting patterns ✓

Python provides several libraries, including Matplotlib and seaborn, for creating density and contour plots

Density plot program:

```
import numpy as np
```

```
import matplotlib.pyplot as plt
```

```
# generate random data for demonstration plot
```

```
np.random.seed(0)
```

```
x = np.random.randn(1000)
```

```
y = np.random.randn(1000)
```

```
# create a density plot (2D histogram)
```

```
plt.hist2d(x, y, bins = (40, 40), cmap = 'Blues')
```

```
plt.colorbar()
```

```
plt.title('Density plot')
```

```
plt.xlabel('x-axis')
```

```
plt.ylabel('y-axis')
```

```
plt.show()
```

meshgrid:

```
import matplotlib.pyplot as plt
```

```
plt.style.use('seaborn-white')
```

```
import numpy as np
```

```
def f(x,y):
```

```
    return np.sin(x)**12 + np.cos(15+y*x) *
```

```
x = np.linspace(0,5,30)
```

```
y = np.linspace(0,5,60)
```

```
x,y = np.meshgrid(x,y)
```

```
z = f(x,y)
```

```
plt.contour(x,y,z, colours='blue');
```

```
plt.contour(x,y,z,20, cmap='Blues');
```

to change full color into blue!

As the same coding, add,

```
plt.contourf(x, y, z, 20, cmap='Blues')
```

```
plt.colorbar(); # blue regions are "peaks"
```

white regions are

↓  
"valleys".

show the color  
variation in the  
plot diagram.

(In simple words,

dark lines are peaks

dotted lines are valleys.)

plt.imshow:

```
contours = plt.contour(x, y, z, 3, colors='blue')
```

```
plt.clabel(contours, inline=True, fontsize=10)
```

```
plt.imshow(z, extent=[0, 7, 0, 7], origin='lower',  
cmap='Blues', alpha=0.7)
```

```
plt.colorbar();
```

↓  
It is used to show  
the image in semi-  
transparent.

Distribution:

Distribution refers to the way data is spread or organized within a dataset.

Histograms, box plots, density plots, and quantile-quantile (Q-Q) plots are commonly used visualizations to understand and represent data distributions.

Distributions are widely used in various fields, including finance, engineering, social sciences, biology, and more, to model and analyze real-world data.

Histogram:

> A histogram is a graphical representation of the distribution of a dataset.

> Data is divided into intervals or "bins", and the number of data points that fall into each bin is represented as bars or rectangles.

Bins: The range of data values is divided into several intervals or bins.

Frequency: The height of each bar or rectangle in the histogram.

continuous data. Histograms are commonly used to represent continuous data, such as measurements, but they can also be used for discrete data.

Uses:

- > gaining insights into the distribution of data
- > identifying patterns (or) outliers
- > understanding the central tendency and spread of the dataset.

Various fields:

Statistics  
data analysis  
data visualization.

# Sample code for histogram:

```
import matplotlib.pyplot as plt
import numpy as np
```

```
# Generate 1000 random data
```

```
data = np.random.randn(1000)
```

```
# create a histogram
```

```
plt.hist(data, bins=20, color='skyblue',  
edgecolor='black')
```

```
plt.xlabel('Value')
```

```
plt.ylabel('Frequency')
```

```
plt.title('Histogram Example')
```

```
plt.grid(True)
```

```
plt.show()
```

code to show students weight.

```
import matplotlib.pyplot as plt
import numpy as np.
```

```
# generate a random weight data for a
group of people.
```

```
np.random.seed(0) # For reproducibility.
```

```
mean_weight = 70 # Mean weight in kg
```

```
std_deviation = 10 # sd in kg
```

```
num_samples = 100
```

```
weights = np.random.normal(mean_weight,
                             std_deviation, num_samples).
```

```
# create a histogram.
```

```
plt.hist(weights, bins = 25, color = 'light blue',
          edgcolor = 'black').
```

```
plt.xlabel('weight (kg)')
```

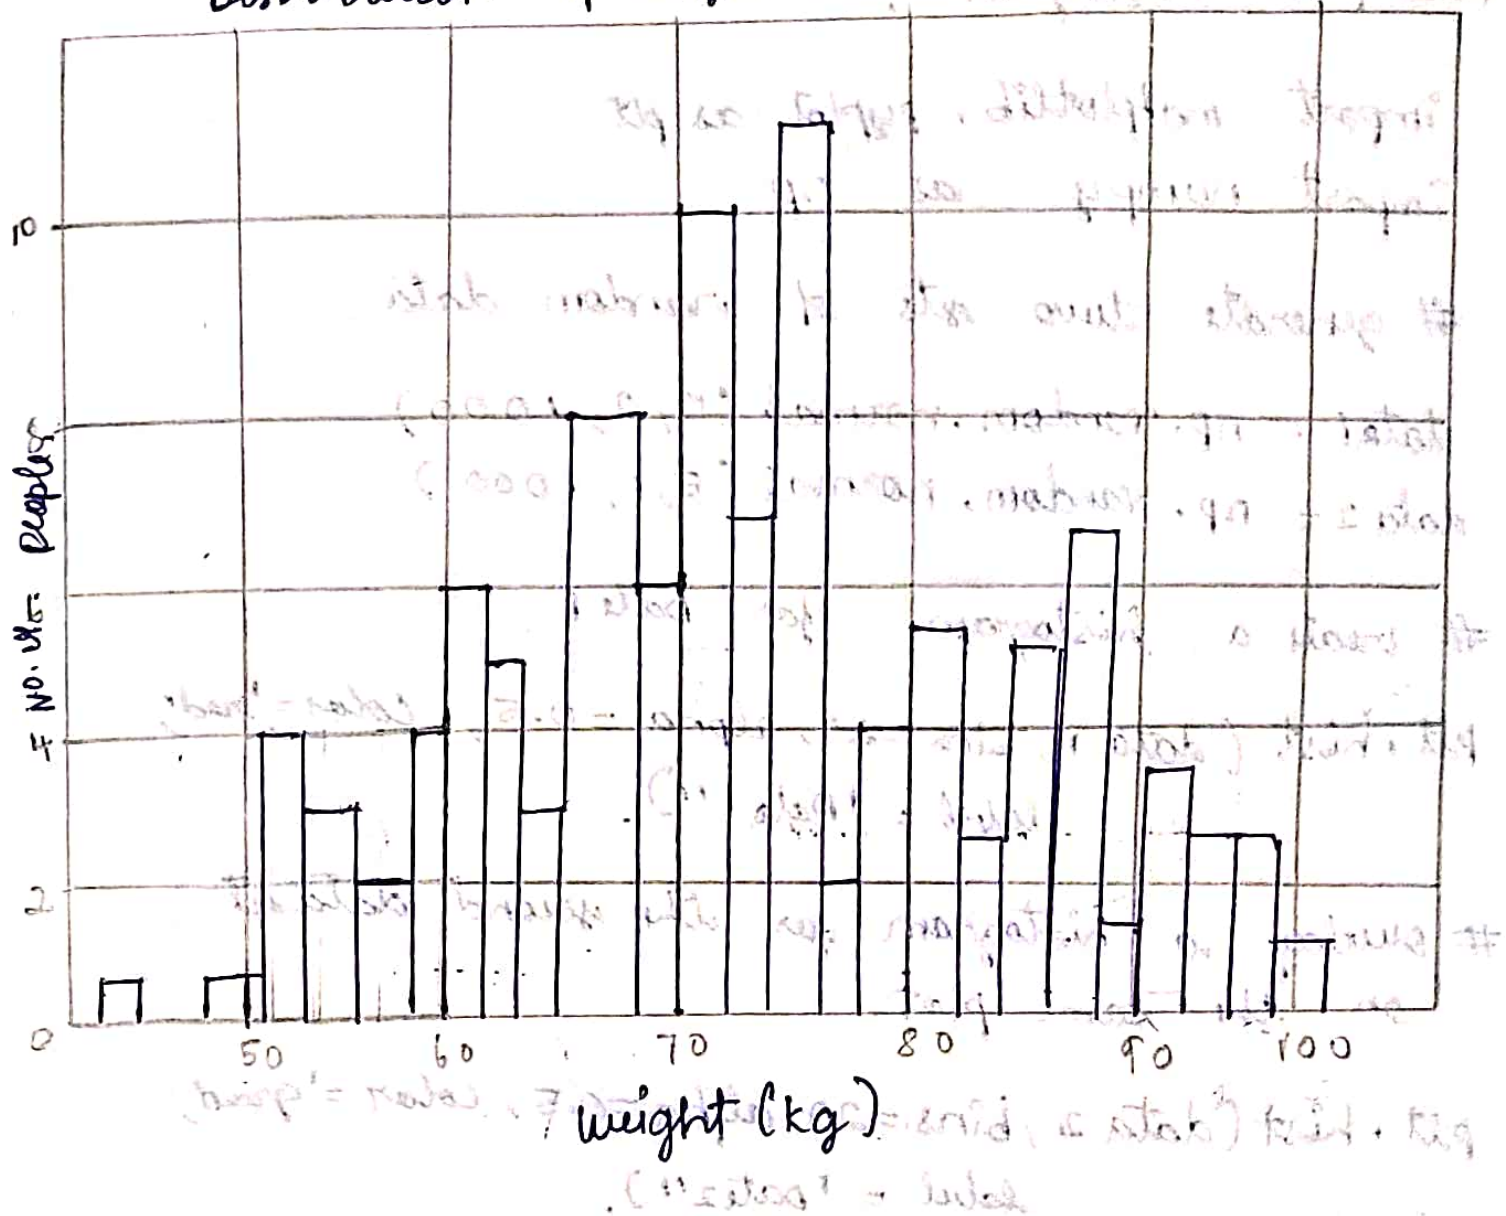

```
plt.ylabel('No. of people')
```

```
plt.title('Distribution of weight in a group
of people')
```

```
plt.grid(True).
```

```
plt.show()
```

## Distribution of weight in a group of people

Eg -2:

```
import matplotlib.pyplot as plt
```

```
import numpy as np.
```

```
plt.style.use('seaborn-white')
```

```
data = np.random.randn(1000)
```

```
plt.hist(data, bins=20, density=True, alpha=0.7,
         histtype='stepfilled', color='blue',
         edgecolor='green')
```

```
plt.show()
```

## Multiple Histogram:

```
import matplotlib.pyplot as plt.  
import numpy as np  
# generate two sets of random data.  
data1 = np.random.normal(0, 2, 1000)  
data2 = np.random.normal(5, 1, 1000)  
# create a histogram for data1.  
plt.hist(data1, bins=20, alpha=0.5, color='red',  
         label='Data1')  
# overlay a histogram for the second dataset  
on the same plot.  
plt.hist(data2, bins=20, alpha=0.5, color='green',  
         label='Data2')  
plt.xlabel('Value')  
plt.ylabel('Frequency')  
plt.title('Overlaying Multiple Histograms')  
plt.legend()  
plt.grid(True)  
plt.show()
```

## overlapping Multiple Histograms

## Legends in a Matplotlib:

Legends in a Matplotlib plot provide additional information about the elements on the plot, such as the meaning of different colors, line styles, or markers to improve the clarity of the plot.

It easier for viewers to understand the data.

Legend explore :

```
import matplotlib.pyplot as plt  
import numpy as np.
```

```
# sample data
```

```
x = np.arange(1,6)
```

```
y1 = np.arrangey([10, 12, 5, 8, 9])
```

```
y2 = np.array([8, 6, 12, 7, 10])
```

```
# create a line plot with two lines.
```

```
plt.plot(x, y1, label='Data1', marker='o',  
         color='b')
```

```
plt.plot(x, y2, label='Data2', marker='s',  
         color='r')
```

```
# Add a legend
```

```
plt.legend()
```

```
plt.title('Line Plot with Legend')
```

```
plt.xlabel('x-axis')
```

```
plt.ylabel('y-axis')
```

```
plt.show()
```

## Line plot with Legend

## Colors :

In Matplotlib, colors can be specified in several ways,

- > by name

- > hexadecimal RGB Value

- > float value between 0 and 1

- > RGB or RGBA color.

## By Name :

```
plt.plot(x, y, color = 'red')
```

## Hexadecimal RGB Value

```
plt.plot(x, y, color = '#FF5733')
```

# Bayesian Data Analysis!

problem definition  $\rightarrow$  data collection  $\rightarrow$

Model development  $\rightarrow$  prior distribution  $\rightarrow$

Data Analysis  $\rightarrow$  Results communication.

## Prior distribution:

Before observing any data, we need to specify prior distributions.

For the model parameters, let's

assume a weakly informative prior

for  $\beta$ , such as a normal distribution

centered at 0 with moderate

standard deviation  $\sigma$

---

$$\frac{50 \times 70}{100} = 35$$

35

$$\frac{50 \times 30}{100} = 15$$

15

## Contingency Table :

gender (Male / Female)  $\rightarrow$  Voting preference (A/B).

	Voting A	Voting B	Total
Male	30	20	50
Female	40	10	50
Total	70	30	100

$70 + 30 = 100$

### 1. Examine the Table :

> Observe the counts in each cell, noting the distribution of responses.

### 2. Row & column Margins:

> Calculate row & column Totals to identify the marginal distributions.

> Row Marginal (Total in each row): 50, 50, 100.

> Column Margins (Total in each column): 70, 30, 100.

### 3. Calculate Percentages:

> compute Percentages For each cell,  
row, & column.

> cell percentage (eg. Male who voted A)

$$30/100 \times 100 = 30\%$$

> Row Percentage (eg. Male who voted  
A out of Male Total)

$$30/50 \times 100 = 60\%$$

> column Percentage (eg. Male who  
voted A out of total who voted A)

$$30/70 \times 100 = 42.86\%$$

#### 4. Assess Independence:

> Examine: whether the distribution of  
one variable is independent of the  
other or if there is an association.

#### 5. Chi-Square Test:

> use the chi-Square test to determine  
if there is a significant association  
between the variables.

> calculate the chi-square statistic & compare it to the critical value.

## 6. Interpretation Results:

> If the p-value from the chi-square test is significant, reject the null hypothesis of independence.

## 7. Visualization:

$$dof = (r-1)(c-1)$$

> create visualizations like a clustered bar chart or a stacked bar chart to illustrate the relationships visually.

O	E	O-E	$(O-E)^2$	$\frac{(O-E)^2}{E}$
30	35	-5	25	0.71
40	35	5	25	0.71
20	15	+5	25	1.66
10	15	-5	25	1.66
				4.74
